0.1.1 Delayed Simulation Game

In this section we consider delayed simulation games and variants thereof on DPAs. This approach is based on the paper [1], which considered the games for alternating parity automata. The DPAs we use are a special case of these APAs and therefore worth examining.

Definition 0.1.1. For convenience, we define two orders for this chapter. First, we introduce \checkmark as an “infinity” to the natural numbers and define the **obligation order** $\leq_{\checkmark} \subseteq (\mathbb{N} \cup \{\checkmark\}) \times (\mathbb{N} \cup \{\checkmark\})$ as $0 \leq_{\checkmark} 1 \leq_{\checkmark} 2 \leq_{\checkmark} \dots \leq_{\checkmark} \checkmark$.

Second, we define an order of “goodness” on parity priorities $\preceq_p \subseteq \mathbb{N} \times \mathbb{N}$ as $0 \preceq_p 2 \preceq_p 4 \preceq_p \dots \preceq_p 5 \preceq_p 3 \preceq_p 1$.

Definition 0.1.2. Let $\mathcal{A} = (Q, \Sigma, q_0, \delta, c)$ be a DPA. We define the *delayed simulation automaton* $\mathcal{A}_{\text{de}}(p, q) = (Q_{\text{de}}, \Sigma, (p, q, \gamma(c(p), c(q), \checkmark)), \delta_{\text{de}}, F_{\text{de}})$, which is a deterministic Büchi automaton, as follows.

- $Q_{\text{de}} = Q \times Q \times (\text{img}(c) \cup \{\checkmark\})$, i.e. the states are given as triples in which the first two components are states from \mathcal{A} and the third component is either a priority from \mathcal{A} or \checkmark .
- The alphabet remains Σ .
- The starting state is a triple $(p, q, \gamma(c(p), c(q), \checkmark))$, where $p, q \in Q$ are parameters given to the automaton, and γ is defined below.
- $\delta_{\text{de}}((p, q, k), a) = (p', q', \gamma(c(p'), c(q'), k))$, where $p' = \delta(p, a)$, $q' = \delta(q, a)$, and γ is the same function as used in the initial state. The first two components behave like a regular product automaton.
- $F_{\text{de}} = Q \times Q \times \{\checkmark\}$.

$\gamma : \mathbb{N} \times \mathbb{N} \times (\mathbb{N} \cup \{\checkmark\}) \rightarrow \mathbb{N} \cup \{\checkmark\}$ is the update function of the third component and defines the “obligations” as they are called in [1]. It is defined as

$$\gamma(i, j, k) = \begin{cases} \checkmark & \text{if } i \text{ is odd and } i \leq_{\checkmark} k \text{ and } j \preceq_p i \\ \checkmark & \text{if } j \text{ is even and } j \leq_{\checkmark} k \text{ and } i \preceq_p j \\ \min_{\leq_{\checkmark}} \{i, j, k\} & \text{else} \end{cases}$$

Definition 0.1.3. Let \mathcal{A} be a DPA and let \mathcal{A}_{de} be the delayed simulation automaton of \mathcal{A} . We say that a state p *de-simulates* a state q if $L(\mathcal{A}_{\text{de}}(p, q)) = \Sigma^\omega$. In that case we write $p \leq_{\text{de}} q$. If also $q \leq_{\text{de}} p$ holds, we write $p \equiv_{\text{de}} q$.

\equiv_{de} is a congruence relation.

Our overall goal is to use \equiv_{de} to build a quotient automaton of our original DPA. The first step towards this goal is to show that the result is actually a well-defined DPA, by proving that the relation is a congruence.

Lemma 0.1.1. γ is monotonous in the third component, i.e. if $k \leq_{\checkmark} k'$, then $\gamma(i, j, k) \leq_{\checkmark} \gamma(i, j, k')$ for all $i, j \in \mathbb{N}$.

Proof. We consider each case in the definition of γ . If i is odd, $i \leq_{\checkmark} k$ and $j \preceq_p i$, then also $i \leq_{\checkmark} k'$ and $\gamma(i, j, k) = \gamma(i, j, k') = \checkmark$.

If j is even, $j \leq_{\checkmark} k$ and $j \preceq_p i$, then also $j \leq_{\checkmark} k'$ and $\gamma(i, j, k) = \gamma(i, j, k') = \checkmark$.

Otherwise, $\gamma(i, j, k) = \min\{i, j, k\}$ and $\gamma(i, j, k') = \min\{i, j, k'\}$. Since $k \leq_{\checkmark} k'$, $\gamma(i, j, k) \leq_{\checkmark} \gamma(i, j, k')$. \square

Lemma 0.1.2. Let \mathcal{A} be a DPA and let $p, q \in Q, k \in \mathbb{N} \cup \{\checkmark\}$. If the run of \mathcal{A}_{de} starting at (p, q, k) on some $\alpha \in \Sigma^\omega$ is accepting, then for all $k \leq_{\checkmark} k'$ also the run of \mathcal{A}_{de} starting at (p, q, k') on α is accepting.

Proof. Let ρ be the run starting at (p, q, k) and let ρ' be the run starting at (p, q, k') . Further, let p_i, q_i, k_i , and k'_i be the components of the states of those runs in the i -th step. Via induction we show that $k_i \leq_{\checkmark} k'_i$ for all i . Since k_i is \checkmark infinitely often, the same must be true for k'_i and ρ' is accepting.

For $i = 0$, we have $k_0 = k \leq_{\checkmark} k' = k'_0$. Otherwise, we have $k_{i+1} = \gamma(c(p_{i+1}), c(q_{i+1}), k_i)$ and k'_{i+1} analogously. The rest follows from Lemma 0.1.1. \square

Lemma 0.1.3. Let \mathcal{A} be a DPA and $\rho \in Q_{\text{de}}^\omega$ be a run of \mathcal{A}_{de} on some word. Let $k \in (\mathbb{N} \cup \{\checkmark\})^\omega$ be the third component during ρ . For all i , $k(i+1) \leq_{\checkmark} k(i)$ or $k(i+1) = \checkmark$.

Proof. Follows directly from the definition of γ . \square

Lemma 0.1.4. Let \mathcal{A} be a DPA with two states $p, q \in Q$. Let $\alpha \in \Sigma^\omega$ be an ω -word and let ρ_p and ρ_q be the respective runs of \mathcal{A} on α starting in p and q . If $\min \text{Inf}(c(\rho_q)) \preceq_p \min \text{Inf}(c(\rho_p))$, then $\alpha \in L(\mathcal{A}_{\text{de}}(p, q))$.

Proof. \square

Lemma 0.1.5. Let \mathcal{A} be a DPA. Then \leq_{de} is reflexive and transitive.

Proof. For reflexivity, we need to show that $q \leq_{\text{de}} q$ for all states q . This is rather easy to see. For a word $\alpha \in \Sigma^\omega$, the third component of states in the run of $\mathcal{A}_{\text{de}}(q, q)$ on α is always \checkmark , as $\gamma(i, i, \checkmark) = \checkmark$.

For transitivity, let $q_1 \leq_{\text{de}} q_2$ and $q_2 \leq_{\text{de}} q_3$. Assume towards a contradiction that $q_1 \not\leq_{\text{de}} q_3$, so there is a word $\alpha \notin L(\mathcal{A}_{\text{de}}(q_1, q_3))$. We consider the three runs ρ_{12}, ρ_{23} , and ρ_{13} of $\mathcal{A}_{\text{de}}(q_1, q_2)$, $\mathcal{A}_{\text{de}}(q_2, q_3)$, and $\mathcal{A}_{\text{de}}(q_1, q_3)$ respectively on α . Then ρ_{12} and ρ_{23} are accepting, whereas ρ_{13} is not.

Moreover, we use the notation $q_1(i), q_2(i), q_3(i)$ for the states of the run and $k_{12}(i), k_{23}(i), k_{13}(i)$ for the obligations. More specifically for a run ρ_{ij} , it is true that $\rho_{ij}(n) = (q_i(n), q_j(n), k_{ij}(n))$.

As ρ_{13} is not accepting, k_{13} becomes \checkmark only finitely often. By Lemma 0.1.3, that means k_{13} only grows smaller from some point on and reaches a minimum eventually. Let $n_0 \in \mathbb{N}$ be a position such that two requirements are satisfied:

- k_{13} does not change anymore after n_0 , i.e. $i, j \geq n_0$ imply $k_{13}(i) = k_{13}(j)$.
- For all three states q_1 , q_2 , and q_3 , from n_0 on only priorities are seen that occur infinitely often for that respective state.

Let $l_j = \min\{c(q_j(i)) \mid i \geq n_0\}$ be the lowest priority that q_j reaches after n_0 . This is equivalent to $l_j = \min \text{Inf}(\{c(q_j(i)) \mid i \in \mathbb{N}\})$. We now show that $l_3 \preceq_p l_1$. By Lemma 0.1.4 this gives us $\alpha \in L(\mathcal{A}_{\text{de}}(q_1, q_3))$, letting us conclude in a contradiction.

Case 1: l_2 is even. We claim that l_3 is even and $l_3 \leq l_2$.

First, to show $l_3 \leq l_2$, let $m \geq n_0$ be a position with $c(q_2(m)) = l_2$ and let $n \geq m$ be the minimal position with $k_{23}(n) = \checkmark$. If $m = n$, then $c(q_3(n)) \preceq_p c(q_2(n)) = l_2$ and therefore $c(q_3(n)) \leq l_2$. Otherwise, from m to $n - 1$, k_{23} only grows smaller and is at most l_2 . As the priority of q_2 never becomes an odd number smaller than l_2 , the only way for $k_{23}(m)$ to be \checkmark is that $c(q_3(m))$ is even and $c(q_3(m)) \leq k_{23}(m - 1) \leq l_2$.

Second, assume that l_3 is odd and let m be a position with $c(q_3(m)) = l_3$. As l_2 is even, we have $k_{23}(m) \leq l_3 < l_2$. At no future position can $c(q_3)$ both be even and smaller than k_{23} , so k_{23} never becomes \checkmark again. Thus, ρ_{23} is not accepting.

We claim that l_1 is odd or $l_1 \geq l_2$.

Towards a contradiction assume the opposite, so $l_1 < l_2$ and l_1 is even. Let $m \geq n_0$ be a position with $c(q_1(m)) = l_1$. Then $c(q_2(m)) \not\preceq_p c(q_1(m))$ and therefore $k_{12}(m) = l_1$. At no position after m can it happen that the conditions for k_{12} to become \checkmark again are satisfied. Thus, ρ_{12} would not be accepting.

If l_1 is odd and l_3 is even, $l_3 \preceq_p l_1$ follows. For the other case, l_1 and l_3 both being even with $l_3 \leq l_2 \leq l_1$, that also holds.

Case 2: l_2 is odd. We skip the details of this case as it works symmetrically to case 1. In particular, we first show that l_1 is odd and $l_1 \leq l_2$. We continue with l_3 being even or $l_3 \geq l_2$. From these two statements, $l_3 \preceq_p l_1$ again follows. \square

Theorem 0.1.6. *Let \mathcal{A} be a DPA. Then \equiv_{de} is a congruence relation.*

Proof. The three properties that are required for \equiv_{de} to be an equivalence relation are rather easy to see. Reflexivity and transitivity have been shown for \leq_{de} already and symmetry follows from the definition. Congruence requires more elaboration.

Let $p \equiv_{\text{de}} q$ be two equivalent states. Let $a \in \Sigma$ and $p' = \delta(p, a)$ and $q' = \delta(q, a)$. We have to show that also $p' \equiv_{\text{de}} q'$. Towards a contradiction, assume that $p' \not\equiv_{\text{de}} q'$, so there is a word $\alpha \notin L(\mathcal{A}_{\text{de}}(p', q'))$. Let $(p', q', k) = \delta_{\text{de}}((p, q, \checkmark), a)$. By Lemma 0.1.2, the run of \mathcal{A}_{de} on α from (p', q', k) cannot be accepting; otherwise, the run of \mathcal{A}_{de} from (p, q, \checkmark) would be accepting and $\alpha \in L(\mathcal{A}_{\text{de}}(p, q))$. Hence, $a\alpha \notin L(\mathcal{A}_{\text{de}}(p, q))$, which means that $p \not\equiv_{\text{de}} q$. \square

We want to mention here that \equiv_{de} is actually an equivalence relation on APAs as well, as was shown in the original paper. However, congruence is the key point at which deterministic automata diverge. Congruence requires something to be true for *all* successors of a state; delayed simulation only requires there to be *one* equivalent pair of successors. Only in deterministic automata is it that these two coincide.

Corollary 0.1.7. *Let \mathcal{A} be a DPA and \equiv_{de} the corresponding delayed simulation-relation. The quotient automaton \mathcal{A}/\equiv_{de} is well-defined and deterministic.*

Correctness of the quotient

The quotient automaton itself is used “only” for state space reduction. The main point of delayed simulation is that the priorities of equivalent states can be made equivalent.

Theorem 0.1.8. *Let $\mathcal{A} = (Q, \Sigma, q_0, \delta, c)$ be a DPA. Let $\sim \subseteq Q \times Q$ be a congruence relation such that $p \sim q$ implies $c(p) = c(q)$. Then $L(\mathcal{A}) = L(\mathcal{A}/\sim)$.*

Proof. Since \mathcal{A} is deterministic and \sim is a congruence relation, $\mathcal{A}/\sim = (Q/\sim, \Sigma, [q_0]_\sim, \delta_\sim, c_\sim)$ is deterministic as well. Let $\alpha \in \Sigma^\omega$ be a word and let π and ρ be the runs of \mathcal{A} and \mathcal{A}/\sim .

For each $i \in \mathbb{N}$, we have $\rho(i) = [\pi(i)]_\sim$ and $c_\sim(\rho(i)) = c(\pi(i))$. Thus, $\text{Inf}(c(\pi)) = \text{Inf}(c(\rho))$ and π is accepting iff ρ is accepting. \square

Lemma 0.1.9. *Let \mathcal{A} be a DPA and let π and ρ be runs of \mathcal{A} on the same word but starting at different states. If $\pi(0) \equiv_{de} \rho(0)$, then $\min \text{Occ}(c(\pi)) = \min \text{Occ}(c(\rho))$.*

Proof. We do a prove by contradiction. Let $k = \min \text{Occ}(c(\pi))$ and $l = \min \text{Occ}(c(\rho))$. Assume without loss of generality that $k < l$. Let α be the word that is read by the two runs.

If k is even, let σ be the run of $\mathcal{A}_{de}(\pi(0), \rho(0))$ on α . Let n be a position at which $c(\pi(0)) = k$. We claim that for all $i \geq n$, the third component of $\sigma(i)$ is k .

At $\sigma(n)$, this must be true because $k < l \leq c(\rho(n))$ and thus $c(\rho(n)) \not\leq_p c(\pi(n))$. At all positions after n , it can never occur that $c(\rho(i))$ is at most k or that $c(\pi(i))$ is odd and smaller than k . The rest follows from the definition of γ .

If k is odd, we can argue similarly on the run of $\mathcal{A}_{de}(\rho(0), \pi(0))$. As soon as $c(\pi)$ reaches its minimum, the third component of the run will never change again. \square

Theorem 0.1.10. *Let $\mathcal{A} = (Q, \Sigma, q_0, \delta, c)$ be a DPA and let $p, q \in Q$ with $p \equiv_{de} q$ and $c(p) < c(q)$.*

Define $\mathcal{A}' = (Q, \Sigma, q_0, \delta, c')$ with $c'(s) = \begin{cases} \min c(p) & \text{if } s = q \\ c(s) & \text{else} \end{cases}$. Then $L(\mathcal{A}) = L(\mathcal{A}')$.

Proof. First, consider the case that $c(p)$ is an even number. The parity of each state is at least as good in \mathcal{A}' as it is in \mathcal{A} , so $L(\mathcal{A}) \subseteq L(\mathcal{A}')$. For the other direction, assume there is a $\alpha \in L(\mathcal{A}') \setminus L(\mathcal{A})$, so the respective run $\rho \in Q^\omega$ is accepting in \mathcal{A}' but not in \mathcal{A} .

For this to be true, ρ must visit q infinitely often and $c'(q)$ must be the lowest priority that occurs infinitely often; otherwise, the run would have the same acceptance in both automata. Thus, there is a finite word $w \in \Sigma^*$ such that from q , \mathcal{A} reaches again q via w and inbetween only priorities greater than $c'(q)$ are seen.

Now consider the word w^ω and the run π_q of \mathcal{A} on said word starting in q . With the argument above, we know that the minimal priority occurring in $c(\pi)$ is greater than $c'(q)$. If we take the run π_p on w^ω starting at p though, we find that this run sees priority $c(p) = c'(q)$ at the very beginning. This contradicts Lemma 0.1.9, as $p \equiv_{de} q$. Thus, the described α cannot exist.

If $c(p)$ is an odd number, a very similar argumentation can be applied with the roles of \mathcal{A} and \mathcal{A}' reversed. We omit this repetition. \square

Corollary 0.1.11. *For a DPA \mathcal{A} , the quotient automaton \mathcal{A}/\equiv_{de} is a DPA that recognizes the same language.*

0.1.2 Using delayed simulation for APAs
